Dynamics of multi-component fermions in optical lattices —
•JASPER SIMON KAUSNER, JANNESE HENNING, NICK FLASCHNER, SÖREN GöTZE, CHRISTOPH BECKER, and KLAUS SENGSTOCK — Universität Hamburg, Institut für Laser-Physik, Luruper Chaussee 149, 22761 Hamburg, Germany

Quantum gases in optical lattices offer a wide range of applications for quantum simulation due to the full control over lattice and interaction parameters as well as the internal atomic degrees of freedom. In our setup, we produce different interacting spin mixtures of fermionic potassium atoms and load them into an optical lattice. The atoms behave similar to electrons in a crystal. However, in contrast to electrons with spin-1/2, we use ⁴⁰K with a higher spin, which has important effects on the properties of the system. The atomic ensemble is quenched from a populated to a non-polarized regime and the resulting dynamics are recorded. We compare our data to a theoretical calculation. In the latter, we assume a simplified two-particle model which is in very good agreement with our observations. Our results open new perspectives to study magnetism of fermionic lattice systems beyond conventional spin-1/2 systems.

Pairing in a few-fermion system with attractive interactions —
•THOMAS LOMPIE1,2, GERHARD ZORN1,2, FRIEDHELM SERWANE1,2, ANDRE WENZ1,2, VINCENT KLINKHAMMER1,2, and SELIM JOCHM1,2 — 1Physikalisches Institut, Universität Heidelberg — 2MPI für Kernphysik, Heidelberg

Recently, our group has demonstrated the ability to prepare small samples of neutral fermionic atoms confined in an optical microtrap [1,2]. We can control the particle number and the motional quantum state of the particles with near unity fidelity. Here we report on our studies of systems consisting of atoms in two spin states with attractive inter-particle interactions. We probe the system by deforming the trapping potential and observing the tunneling of particles out of the trap. We observe several signatures of pairing such as an increase of the tunneling time constants for stronger interactions and the appearance of pair correlations in the tunneling. With our tunneling measurements we also observe strong differences between systems with odd and even particle numbers. This is similar to the odd-even effect observed for the binding energies of nuclei.

Conduction of ultracold Fermions through a mesoscopic channel —
•DAVID STADLER, JEAN-PHILIPPE BRANTJUT, JAKOB MINERKE, SOPHIE M. KÖHLER, KRISTIN WILMANN, and CARSTEN ROHDE — Quantum Electronics, ETH Zürich, 8093 Zürich, Switzerland

We present a measurement of ultracold Fermions flowing through a horizontally oriented quasi 2-dimensional constriction which is connected to two macroscopic atom reservoirs. The constriction is made by a blue detuned laser beam that has a TEM01 mode, where atoms can only stay in a thin region of about 300nm between the two intensity maxima. A controlled imbalance of the number of atoms in the two reservoirs induces then a current of atoms from one side to the other. We observe the current of atoms as a function of time and see a characteristic decay of the atom number imbalance to its equilibrium position with equal atom number in both reservoirs. Secondly, we image the central part between the reservoirs where the 2-dimensional constrictions is located. With our high-resolution imaging system we are able to atomically resolve the density distribution of atoms in the presence of a current. This gives us insight into the physical mechanisms that take place in the constriction and at the contacts to the reservoirs. We investigated the current of atoms in two very different situations. One is ballistic flow where we only have the quasi 2-dimensional constriction and the other is diffusive flow. Even though the macroscopic current of atoms is the same, we see a very different local behaviour of the atomic density in the constriction and at the contacts.

Q 7.4 Mon 14:45 V47.02
Towards local probing of two-dimensional Fermi gases —
•WOLF WEIMER, KAI MONGKEIN, JAN HENNING DREWES, NIELS STROHMAIER, and HENNING MORITZ — Universität Hamburg, Institut für Laserphysik, Luruper Chaussee 149, 22761 Hamburg, Germany

Ultracold fermionic gases are an ideal model system for the study of quantum many-body phenomena. Of particular interest are two-dimensional strongly correlated systems which can exhibit superfluidity and Berezinskii-Kosterlitz-Thouless-type transitions. Here we present our new experimental setup aimed at studying two-dimensional strongly interacting Fermi gases. Lithium atoms are cooled all-optically using an in vacuo bow-tie resonator for high trans-mittance and cooling efficiency. A quantum degenerate gas will then be placed between two high-resolution microscope objectives for local readout and control. The present status of the experiment will be discussed.

Q 7.5 Mon 15:00 V47.02
Fulde-Ferrel-Larkin-Ovchinnikov phase separation in a onedimensional superconducting lattice of strongly coupled fermions —
•VIJAY FRANÇA and ANDREAS BUCHLEITNER — Physikalisches Institut, Albert-Ludwigs Universität, Freiburg, Germany

The exotic coexistence of superconductivity and magnetism, first investigated by Fulde-Ferrel and Larkin-Ovchinnikov (FFLO), is predicted to show a spontaneous breaking of spatial symmetry. In spin-imbalanced fermionic systems, such inhomogeneous superfluidity manifests in a microscale phase separation, with alternating finite-momentum pairs and normal regions, the latter being composed by the excess species. After almost fifty years since the FFLO-phase was predicted, the microscale phase separation has not been observed. We deduce an expression for the critical polarization below which the FFLO-state emerges in a one-dimensional lattice with spin-imbalanced populations, and that show its ground-state is indeed microscale phase separated. For strongly interacting systems, we find that the microscale structure can be observed directly in the density profiles. Our results suggest that clear signatures of exotic superfluidity are accessible for state-of-the-art experiments with single-site resolution, as already achieved for bosons.

Q 7.6 Mon 15:15 V47.02
Ultracold Driven Fermi gases: Population Trapping and Bloch Oscillations —
•REGINE FRANK — Institut für Theoretische Festkörperfysik, Wolfgang-Göpfert-Strasse 1, Karlsruhe Institute of Technology (KIT), 76131 Karlsruhe, Germany

Ultracold gases are quite perfect to study physical systems under various aspects in situations far off the thermodynamical equilibrium. The two major reasons are that the properties of ultracold gases in optical lattices can be experimentally controlled almost without restrictions and the pronounced lack of dissipative coupling to the environment. In recent years, a three dimensional optical lattice with strength modulations in time and loaded with an interacting gas of fermionic atoms. The inter-atomic correlation strength is varied from weak to strong and the temporal lattice modulations are taken into account by means of an non-equilibrium dynamical mean field theory (DMFT) incorporating the Keldsh Green’s function technique. The numerical results for both the fluid (conducting) and the insulating regime, include the spectral weight function, the non-equilibrium distribution function, the optical conductivity and the relaxation time of the excited atoms. We show the effects of population trapping in gaps and Bloch oscillations of the ultracold fermions.

Q 7.7 Mon 15:30 V47.02
Robustness of Topological Operations with Ultracold Atoms —
•LEONARDO MAZZA1, MATTEO RIZZI1, HONG-HAO TU1, MIKHAIL LUKIN2, and J.Ignacio CIRAC1 — 1Max-Planck-Institut für Quantenoptik, Garching, Germany 2Harvard University, Cambridge, USA

Since the discovery of the quantum Hall effect, topological states have influenced the research of diverse communities. Among their exotic properties, quasiparticles obeying unconventional statistics, called anyons, are surely one of the most seducing. Their braiding, i.e. controlled exchange of positions, has been proposed as possible implementation for quantum computation.

Here we discuss the robustness against different sources of noise...
of information processing and storing of two topological models, the Majorana-Kitaev chain and the p+ip model. We also propose a setup based on fermionic atoms and molecules where both models are realized and anyons can be manipulated.

Q 7.8 Mon 15:45 V47.02

Low-Lying Excitation Modes of a Dipolar Fermi Gas: From Collisionless to Hydrodynamic Regime — Falk Wächtler, Aristeu Lima, and Axel Pelster — Institut für Physik und Astronomie, Universität Potsdam, Germany — Departamento de Física - Universidade Federal do Ceará, Fortaleza - Brazil — Hanse-Wissenschatskolleg, Delmenhorst, Germany

By means of the Boltzmann-Vlasov equation we investigate dynamical properties of a trapped dipolar Fermi gas. In order to determine an approximative solution, we follow Ref. [1] and rescale both space and momentum variables, thus obtaining ordinary differential equations for the respective scaling parameters. Then, we proceed by linearizing these equations around the equilibrium in order to study the low-lying excitations of the system. Within the relaxation-time approximation for the collisional integral, our approach is able to describe the low-lying excitations all the way from the collisionless [2] to the hydrodynamic [3] regime.
