MO 3: Cold Molecules I

Time: Monday 10:30–13:00 Location: BAR Schön

MO 3.1 Mon 10:30 BAR Schön

Ultracold and dense samples of ground-state molecules —
•Johann Georg Danzl, Manfred Mark, Elmar Haller, Lukas
Reichsöllner, and Hanns-Christoph Nägerl — Institut für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria

We produce ultracold and dense samples of rovibrational ground state
(RGS) molecules near quantum degeneracy in the presence of an optical lattice. We first associate Cs_2 Feshbach dimer molecules out
of a lattice-based Mott-insulator state loaded from an atomic Bose-
Einstein condensate (BEC) of Cs atoms and then coherently transfer
the molecules to the RGS by a four-photon STIRAP process. We discuss improvements to reach higher transfer efficiencies and the next
steps towards the production of a BEC of dimer molecules. The work
is supported by the Austrian Science Fund FWF in the framework of
project P 21555-N20.

MO 3.2 Mon 10:45 BAR Schön

Bogoliubov Theory of Dipolar Bose-Einstein Condensates
— •Aristeu R. P. Lima[1] and Axel Pelster[2] — [1]Institut für
Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195
Berlin, Germany — [2]Fachbereich Physik, Universität Duisburg-Essen,
Lotharstrasse 1, 47048 Duisburg, Germany

Nowadays, Bose-Einstein condensates with a weak anisotropic and
long-range dipole-dipole interaction, such as ^{52}Cr condensates, are considered to be relatively well understood in terms of the Gross-Pitaevskii
mean-field theory. Howerever, for highly magnetic atoms, such as dysprosium, or for strongly polar heteronuclear molecules, as for instance
^{40}K-^{87}Rb, quantum fluctuations in dipolar condensates could become
relevant. To this end, we discuss at first the Lee-Huang-Yang correction to the sound velocity of a homogeneous dipolar condensate as
derived from the Bogoliubov theory. In order to take the harmonic
trapping potential into account, we extend our calculations with the
help of the Bogoliubov-de Gennes theory. Thereby, we make use of the
local density approximation to derive the Bogoliubov spectrum analytically, from which we determine then physical quantities of interest
such as the condensate depletion and the quantum corrections to the
low-lying excitation frequencies as well as to the time-of flight dynamics. Due to the delicate interplay between the dipolar interaction and
the condensate geometry, we find that the influence of the quantum
fluctuations can be strongly affected by the trap aspect ratio. Therefore, we are quite optimistic that future experiments will detect these
beyond mean-field effects.

MO 3.3 Mon 11:00 BAR Schön

Semiclassical model for the formation of Rydberg molecules
— •Andrej Junginger, Jörg Main, and Günter Wunner — 1.
Institut für Theoretische Physik, Universität Stuttgart

In cold gases ultra-long range Rydberg molecules have been predicted
theoretically [1] and recently observed experimentally [2]. The bond is
caused by a scattering process of the Rydberg electron at the ground
state atom. In a mean-field approximation this can be explained by a
Fermi pseudo-potential which well describes the bound states but, as
a conservative potential, is not able to explain the process of capturing
the ground state atom.

We present a new model based on scattering theory and a semiclassical approximation which is capable of describing the formation of the
Rydberg molecule by decelerating the ground state atom. From the
infinite set of Kepler ellipses we select a finite number passing through
the ground state atom. At the position of the latter the ellipses are approximated by plane waves, and the s-wave scattering of the Rydberg
electron at the ground state atom then leads to a dissipative force.
Solving the classical equations of motion, we find that a ground state
atom with kinetic energy $E_{kin} > 0$ in the order of the magnitude of
the binding energy will always be decelerated. Depending on the initial conditions it can even come to rest, so that this dissipative process
may play an important role in the formation of the Rydberg molecule.

**Optical Manipulation of Large Molecule Beams for Molecule
Interference** — •Paul Venn and Hendrik Ulbricht — School of

Physics and Astronomy, University of Southampton, Highfield, SO17
1BJ, UK

A challenge of molecule interferometry is being able to create intense
beams of large molecules, which are typically created through sublimation in a furnace. In order to increase the intensity of the beam
reaching our Talbot-Lau interferometer a molecular lens is proposed.
This lensing effect relies on creating an off-resonant Stark shift in the
target molecule species through the interaction with an intense laser
beam directed perpendicular to the molecular beam. This lensing effect has previously been observed for light molecules such as CS2 and
I2, and the effect is scalable up to much larger masses due to the nonresonant interaction. Simulations have been carried out modelling the
lensing effect for our interferometer using a femtosecond pulsed Ti:Sa
laser with 50kW peak power. From this we expect to observe a 25%
increase in detected signal for a thermal beam of C60 using a single
laser beam acting as a cylindrical molecular lens. For more highly polarizable molecules such as H2TPP we expect to be able to observe
the focal spot of the lens without the need for preliminary cooling of
the molecule beam. It is hoped that this lensing effect can be used on
more massive fluro-fullerene molecules to allow us to measure interference for molecules of masses of up to 10,000amu. We will report on
theoretical simulations as well as on experiments on this effect.

MO 3.5 Mon 11:30 BAR Schön

**Low temperature studies of molecules in solid state using an
optical nanofiber** — •Ariane Stiebeiner, Nils Konken, David
Papencordt, Ruth Garcia-Fernandez, and Arno Rauschenbeutel — Technische Universität Wien - Atominstitut, Stadionallee 2,
1020 Wien, Austria

Molecules in solids have proven to be a versatile system for studying
quantum optical effects and for realizing single photon sources. Coupling the emitters to optical nanofibers further enhances the potential
of this system. The strong radial confinement and the pronounced
evanescent field of the guided light in optical nanofibers yield a high
excitation and emission collection efficiency [1, 2]. We present low
temperature studies on terrylene doped p-terphenyl crystals on the
nanofiber waist of a tapered optical fiber. The high sensitivity of our
method should allow us to perform single molecule spectroscopy and
to realize an all-fiber-based single photon source.

We gratefully acknowledge financial support by the Volkswagen
Foundation (Lichtenberg Professorship), the ESF (European Young
Investigator Award), and the EC (STREP "CHIMONO").

MO 3.6 Mon 11:45 BAR Schön

Low Temperature Studies on Single Molecules interacting with Plasmonic Structures — •Bernhard Grotz[1], Ilja
Gerhardt[1,2], Petr Siyushev[1], Fedor Jelezko[1], and Jörg
Wrachtrup[1] — [1]3rd Physics Institute and Research Center SCoPE,
Universität Stuttgart, Germany — [2]Max Planck Institute for Solid
State Research, Stuttgart, Germany

When light interacts with metal surfaces it excites electrons which
can form propagating excitation waves called surface plasmon polaritons (SPP). These collective electronic excitations allow for many applications due to their ability to produce electric fields, localized to
sub-wavelength scales. It was shown that the emission of single quantum systems like e.g. quantum dots [1] or nitrogen vacancy centres in
diamond [2] can be used to generate propagating single surface plasmon polaritons. In the frame of large scale quantum networks, further
conceived experiments incooperate the incoupling of single narrowband emitters to plasmons. Such single emitters could be organic dye
molecules serving as an element of e.g. a quantum phase gate. Here
we present first experimental results on the coupling of single organic
molecules to silver nanowires at cryogenic temperatures.

MO 3.7 Mon 12:00 BAR Schön

Interlayer superfluidity and scattering in bilayer systems of polar molecules — •Alexander Pikovski[1], Michael Klawunn[1,2], G. V. Shlyapnikov[3], and Luis Santos[1] — [1]Institut für Theoretische Physik, Leibniz Universität Hannover, Appelstr. 2, 30167 Hannover, Germany — [2]INO-CNR BEC Center and Dipartimento di Fisica, Università di Trento, 38123 Povo, Italy — [3]Laboratoire de Physique Théorique et Modèles Statistiques, Université Paris Sud, CNRS, 91405 Orsay, France

We consider fermionic polar molecules in a bilayer geometry. The dipole-dipole interaction between molecules of different layers leads to the emergence of interlayer superfluids. The superfluid regimes range from BCS-like fermionic superfluidity to BEC of interlayer dimers. The system shows unusual two-dimensional scattering behaviour [M. Klawunn et al., Phys. Rev. A **82**, 044701 (2010)] and exhibits a peculiar BCS-BEC crossover [A. Pikovski et al., Phys. Rev. Lett. **105**, 215302 (2010)].

MO 3.8 Mon 12:15 BAR Schön

Controlling a Shape Resonance with Non-resonant Laser Light — •Ruzin Aganoglu[1], Mikhail Lemeshko[2], Bretislav Friedrich[2], Rosario González-Férez[3], and Christiane P. Koch[1,4] — [1]Freie Universität Berlin, Institut für Theoretische Physik — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — [3]Universidad de Granada, Facultad de Ciencias, Spain — [4]Universität Kassel, Institut für Physik

A shape resonance is a metastable state that arises from trapping of a part of the scattering wavefunction by the centrifugal barrier. It corresponds to an enhanced pair density of atoms at short internuclear separations, which can be useful for making molecules from atom pairs. For atoms confined in an atom trap, the pair density will be enhanced if the energy width of the resonance matches the atom trap temperature. Herein, we seek to control the energy of a shape resonance by making use of non-resonant laser light. Nonresonant light couples to the polarizability anisotropy of an atom pair and thereby modifies its rotational and vibrational states. We study the effect on the pair density of rubidium and strontium atoms as a function of the pulse duration and intensity of the nonresonant light.

MO 3.9 Mon 12:30 BAR Schön

Near-threshold vibrational bound states in long-range molecules — •Tim-Oliver Müller and Harald Friedrich — Physik Department, TU München, Germany

Interatomic potentials with attractive tails asymptotically vanishing as $-1/r^\alpha$ (with $\alpha > 2$) support at most a finite number of vibrational bound states, and their energies E_v are related to their quantum numbers v via a quantization rule $v_D - v = F(E_v)$, where v_D is the – not necessarily integer – *threshold quantum number*. At near-threshold energies the *quantization function* $F(E)$ is predominantly determined by a contribution $F_{\text{tail}}(E)$ stemming from the potential's tail, which is a universal function depending only on the power α. Quantum effects are important near the dissociation threshold and $F(E)$ differs significantly from the widely used semiclassical expression derived by LeRoy and Bernstein [1]. Explicit analytical expressions for F_{tail} have been presented for to the van der Waals interaction between two neutral polarizable atoms or molecules ($\alpha = 6$) [2] as well as for the dispersion energy occuring in certain diatomic molecular ions ($\alpha = 4$) [3] and recently also for the power $\alpha = 3$ [4], which corresponds to the resonant dipole-dipole interaction between two identical atoms in a homonuclear dimer. Applications to sodium dimers show the importance of correctly including quantum effects near threshold.

MO 3.10 Mon 12:45 BAR Schön

Quantum reflection and localization in bound systems — •Elias Diesen[1] and Jan-Michael Rost[2] — [1]Max-Planck-Institut für Physik komplexer Systeme — [2]Max-Planck-Institut für Physik komplexer Systeme

The phenomenon of quantum reflection is briefly presented and compared to the situation where a similar shape of the underlying potential causes localization of eigenstates in a confining potential. The relation of both these quantum phenomena to the breakdown of semiclassical (WKB) dynamics is discussed. A few physical systems that show such behaviour are presented, among them the ultracold Rydberg dimer, consisting of a ground state and a Rydberg atom [1]. Due to the current rapid development of experimental techniques for the ultracold regime, these phenomena should become more and more accessible to direct experimental investigation.
