

MA 56: Multiferroics and Magnetoelectric coupling II (joint session MA/KFM)

Time: Friday 9:30–11:45

Location: H39

MA 56.1 Fri 9:30 H39

Reversible magnetoelectric interconversion of ferroic domain patterns in (Dy,Tb)FeO₃ — ●EHSAN HASSANPOUR¹, MADS C. WEBER¹, YUSUKE TOKUNAGA², YASUJIRO TAGUCHI³, YOSHINORI TOKURA³, THOMAS LOTTERMOSER¹, and MANFRED FIEBIG^{1,3} — ¹ETH Zurich, Switzerland — ²University of Tokyo, Japan — ³RIKEN CEMS, Japan

Multiferroic materials can show a variety of exquisite effects due to hosting coexisting and complex magnetic and electric orders. Recently it was reported that a ferroelectric domain pattern from one layer is transferred to a ferromagnetic layer in a multiferroic heterostructure[1]. Here we show that we can reversibly interconvert magnetic and ferroelectric domain patterns in a single phase of multiferroic bulk system Dy_{0.7}Tb_{0.3}FeO₃. In this material, it was shown that a ferroelectric polarization is induced as a result of interaction of two magnetic sublattices of iron Fe³⁺ and rare-earth (Dy,Tb) R³⁺ via exchange forces. The strong coupling of these three order parameters creates a variety of composite domains and domain walls. Using magneto-optic imaging, we show that electric field pulses of specific speeds and amplitudes can generate and tune those domains/domain walls. Ultimately, by imprinting a domain pattern in the rare-earth's antiferromagnetic order, we transfer it from the ferromagnetic order of iron to the ferroelectric order and vice versa using magnetic and electric fields, respectively.

Coupled electric and magnetic domains and domain walls in h-RMnO₃ at the microscale — ●MARCELA GIRALDO, THOMAS LOTTERMOSER, and MANFRED FIEBIG — ETH Zurich, Switzerland.

Fundamental understanding of the cross-coupling between ferroic orders at the level of domains and domain walls is crucial for the manipulation of multiferroics. It was shown for the first time on h-RMnO₃ that coupling between ferroelectricity and antiferromagnetism –with order parameters P and l , respectively– occurs in a type-I multiferroic where ferroic orders emerge independently. At the macroscopic scale, it was observed that the antiferromagnetic domain pattern (l) is defined by two independent domain patterns formed by P and the multiferroic order parameter Pl [1]. Albeit, coupling on the microscopic regime, on the level of the ferroelectric vortex domains which are characteristic for these materials has remained under debate. For the first time, we investigate the coupling between electric and magnetic domains in h-RMnO₃ on the microscopic scale using second-harmonic microscopy. We reveal that two of the three order parameters (P , l and Pl) change their sign simultaneously at every domain wall while the third one retains its sign. This confirms the earlier observation [1] that P and Pl form independent domain patterns. In addition, we show a new type of domain wall where P and Pl change their sign, while l remains constant. Our observations solve the open debate about coupling of domains and domain walls at the microscale and add new findings to understand the unique coupling nature in a type-I multiferroic.

Magnetoelectric Polarizability in Magnetic Insulators — ●MAXIMILIAN MERTE^{1,2}, FRANK FREIMUTH¹, STEFAN BLÜGEL¹, and YURIY MOKROUSOV^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

In the field of spintronics, the interaction of insulators with external electromagnetic fields plays a crucial role for future prospects related to fundamental understanding and technological applications of magnetic oxides. In a situation of reduced symmetries, magnetic insulators can exhibit a finite electric polarization. Recently, a semiclassical approach describing the positional shift of Bloch electrons due to interband mixing induced by an external electromagnetic field was proposed [1]. These shifts can be computed via response matrices, which are constructed from interband velocity elements and band energies. Here we want to report on the implementation of this approach by means of Wannier interpolation, which can be applied as a postprocessing step to first-principles calculations performed with the Jülich

DFT code FLEUR [2], an implementation of the FLAPW method. We apply the developed method to the study of magnetoelectric polarizability to selected magnetic insulators.

Artificial multiferroic domain walls in oxide heterostructures — ●ELZBIETA GRADAUSKAITE, MANFRED FIEBIG, and MORGAN TRASSIN — Department of Materials, ETH Zurich, Switzerland

Ferroelectric domain walls possess symmetry-dependent functional properties enabled by confinement. Enhanced conductivity, for instance, is observed in charged domain walls. Regrettably, domain walls of this type are very scarce in nature due to energetically unfavourable electrostatics, which hinders technological development of domain wall nanoelectronics. We propose ferroic thin film oxide interfaces as an alternative. The polar state of BaTiO₃ and BiFeO₃ ferroelectrics can be manipulated via atomically precise surface termination control and monitored with in-situ second harmonic generation (ISHG) during the growth. Using this approach, stable head-to-head and tail-to-tail polarization-oriented configurations of ferroelectric layers can be created. Their interfaces are charged and can be regarded as artificial domain walls. By inserting an ultrathin La_{1-x}Sr_xMnO₃ ferromagnetic film at the junction we design a magnetoelectric multiferroic interface. Using a combination of ISHG and SQUID magnetometry, we show that the interlayer magnetic moment can be enhanced or diminished when the artificial domain wall has a head-to-head or tail-to-tail configuration, respectively. Our work provides new insights into electrical control of magnetism in multiferroic oxide heterostructures.

Complex magnon spectrum of the simple collinear antiferromagnet Co₂Mo₃O₈ — ●STEPHAN RESCHKE¹, DÁNIEL FARKAS², SANDOR BORDÁCS², VLADIMIR TSURKAN¹, and ISTVÁN KÉZSMÁRKI¹ — ¹University of Augsburg, Augsburg, Germany — ²Budapest University of Technology and Economics, Budapest, Hungary

Co₂Mo₃O₈ belongs to a family of hexagonal lattice type-I multiferroics, showing peculiar magnetoelectric effects. In this compound the magnetic Co²⁺ ions are in either tetrahedral or octahedral oxygen coordination and form honeycomb layers in the ab plane. Based on neutron powder diffraction, Co₂Mo₃O₈ is a 4 sub-lattice collinear easy-axis antiferromagnet below $T_N = 42$ K. By THz time-domain spectroscopy measurements the magnon excitation spectra of differently oriented single crystals were investigated in magnetic fields up to 7 T. Interestingly, we observed magnon spectra far more complicated than expected for the proposed simple antiferromagnetic structure, with more than 20 magnon modes. Most of these modes show a splitting for magnetic fields applied along the c axis, which supports the predominantly easy-axis character of the antiferromagnetic state. Furthermore, we also observed directional dichroism for some of the modes, a consequence of the dynamic magnetoelectric effects.

MA 56.6 Fri 10:45 H39

Vacuum encapsulated high frequency magnetic field sensors based on the ΔE effect — ●BENJAMIN SPETZLER¹, FLORIAN NIEKIEL², FABIAN LOPINK², BERNHARD WAGNER², and FRANZ FAUPEL¹ — ¹Kiel University, Kiel, Germany — ²Fraunhofer ISIT, Itzehoe, Germany

Investigations into the ΔE effect of magnetoelastic materials have revealed the exciting promise of detecting low frequency and small amplitude magnetic fields [1]. Typical approaches are based on electrically exciting a resonator by applying an alternating voltage to a magnetoelectric composite structure with soft magnetic properties [2]. Previously presented sensors are operated either in the first or second bending mode with resonance frequencies in the lower kHz regime [3]. Due to the low resonance frequencies and comparatively large quality factors, the bandwidth of these sensors is too small for many biomedical applications. Here, we present vacuum encapsulated cantilever resonators operating at high frequency modes with bandwidths in the kHz regime. In addition to common bending modes, longitudinal and more complex modes are also used. The various modes are analyzed experimentally and theoretically for sensitivity, detection

limit, mechanical properties and loss mechanisms with a comprehensive magneto-electromechanical model. Important consequences for future sensor designs are derived.

MA 56.7 Fri 11:00 H39

High magnetic field phases of magnetoelectric LiFePO₄ and LiNiPO₄ — ●BOTOND FORRAI¹, ATSUHIKO MIYATA², DÁVID SZALLER³, VILMOS KOCSIS⁴, YASUJIRO TAGUCHI⁴, YOSHINORI TOKURA⁴, ISTVÁN KÉZSMÁRKI⁵, and SÁNDOR BORDÁCS¹ — ¹Department of Physics, Budapest University of Technology and Economics, Budapest 1111, Hungary — ²Laboratoire National des Champs Magnétiques Intenses, Toulouse 31400, France — ³Institute of Solid State Physics, Vienna University of Technology, Vienna 1040, Austria — ⁴RIKEN Center for Emergent Matter Science (CEMS), Wako, Saitama 351-0198, Japan — ⁵Zentrum für Elektronische Korrelation und Magnetismus, Institut für Physik, Universität Augsburg

Olivine-type orthophosphates has been attracting much attention due to their strong linear magnetoelectric effect. The low-field magnetic phases giving rise to the magnetoelectric effect are well characterized, however, their high field phase diagrams have not been fully explored. Therefore, we studied the magnetic phases of LiFePO₄ and LiNiPO₄ at 5K by magnetization measurements till their magnetization reach the saturation. The competing exchange interactions leads to several phase transitions in LiNiPO₄, while in LiFePO₄ a single spin-flop transition is detected due to the strong anisotropy. The magnetic phase diagrams are interpreted in a classical mean-field model, which allowed us to identify the key terms in spin Hamiltonian.

MA 56.8 Fri 11:15 H39

Electric field control of the nonreciprocal light absorption in Ba₂CoGe₂O₇ — ●JAKUB VÍT¹, TOOMAS RÕÕM², URMAS NAGEL², JOHAN VIROK², VILMOS KOCSIS^{1,3}, YOSHINORI TOKURA³, ISTVÁN KÉZSMÁRKI^{1,4}, and SÁNDOR BORDÁCS¹ — ¹Budapest University of Technology and Economics, Hungary — ²National Institute Of Chem-

ical Physics And Biophysics, Estonia — ³RIKEN CEMS, Japan — ⁴Experimental Physics 5, University of Augsburg, Germany

In crystalline solids where space inversion and time-reversal symmetries are simultaneously broken, the propagation of (quasi)particles can be different when the wave vector is reversed. Strong nonreciprocal light absorption has been observed on spin-wave excitations of multiferroics, i.e. ferroelectric and magnetic materials, where the sign and the magnitude of the effect were controlled by an external magnetic field. Here, we report an electric-field control of the nonreciprocal light absorption on THz excitations of Ba₂CoGe₂O₇. In the canted antiferromagnetic phase, we demonstrate that an electric field can be used to switch between low- and high-absorption states of magnetoelectric excitations. Our finding can facilitate the use of multiferroics in low-power consumption switchable optical diodes.

MA 56.9 Fri 11:30 H39

Manipulating Coercivity and Magnetization Reversal in Bulk Ferromagnetic Metals with Small Voltages — ●XINGLONG YE, ROBERT KRUK, and HORST HAHN — Institute of Nanotechnology, Karlsruhe Institute of Technology (KIT), Hermann-von-Helmholtz-Platz 1, Eggenstein-Leopoldshafen, 76344, Germany

Voltage control of magnetic properties in ferromagnetic metals is usually restricted to the scale of atomic layer due to their strong electric-field screening. Here we show that magnetic properties of bulk ferromagnetic metals can be hugely and reversibly tuned by small voltages through charging and discharging of hydrogen atoms. We manipulated the coercivity of micrometer-sized ferromagnetic metals by an amplitude of 2500 Oe with voltages only around 1 volt. Through this effect voltage-assisted and -gated magnetization reversal have been demonstrated. Experimental and density functional theory simulation results suggest that this phenomenon originates from the change of magnetocrystalline anisotropy at the surface layers with absorption and desorption of hydrogen atoms, which changes the nucleation field of reversed domains. This work may open up a new route for voltage control of magnetic properties in bulk metals, and voltage-assisted magnetization reversal also has implications for magnetic recording.
